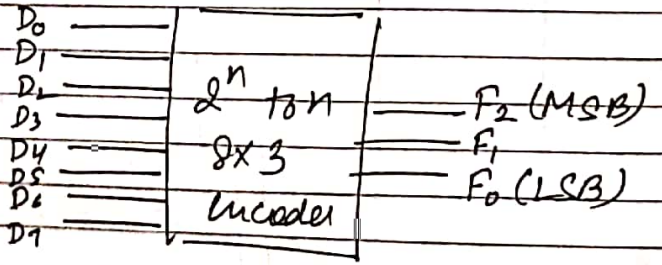
Disadvantages

1. Only one input can be active at any given time
2. If all inputs are zero, there is no valid input

→ These two problems are mainly solved in priority encoder.



$F_0 = D_1 + D_3 + D_5 + D_7$
$F_1 = D_2 + D_3 + D_6 + D_7$
$F_2 = D_4 + D_5 + D_6 + D_7$

Priority Encoder

The operation of priority encoder is such that if two or more inputs are equal to 1 at the same time then the input having the highest priority will take precedence.

A decoder with enabled input can function as demultiplexer which is a circuit that recieves information from a single line and directs it to 2^n possible output lines.

Because decoder and demultiplexer operations are obtained from the same circuit a decoder with an enabled input is also referred as decoder/demultiplexer.

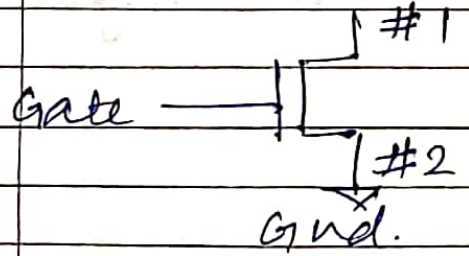
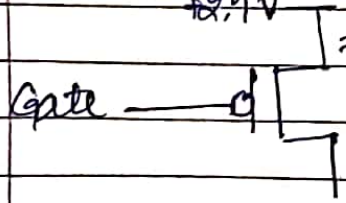
n type MOS transistor



+ve voltage :- switch closed

-ve voltage :- switch open

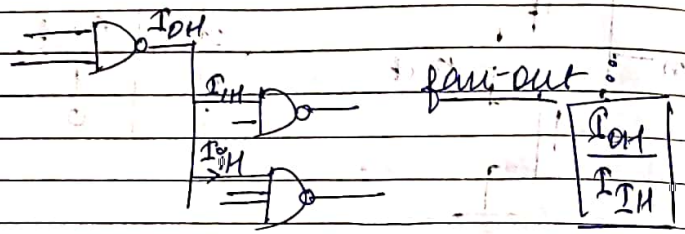
p type MOS transistor



+ve voltage :- switch open

-ve voltage :- switch closed

- no. of inputs that can be connected to the output of a gate



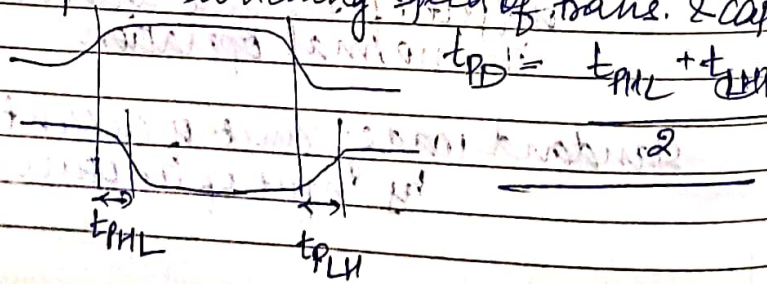
fan-out : $\frac{I_{OH}}{I_{IH}}$

Power dissipation - (mW)
↳ amt of power needed by the gate

$P = V_{CC} \times I_{CC}$
V_{CC} → voltage supply
I_{CC} → current drawn from gate.

$I_{CC(avg.)} = \frac{I_{CC \text{ at high voltage}} + I_{CC \text{ low voltage}}}{2}$

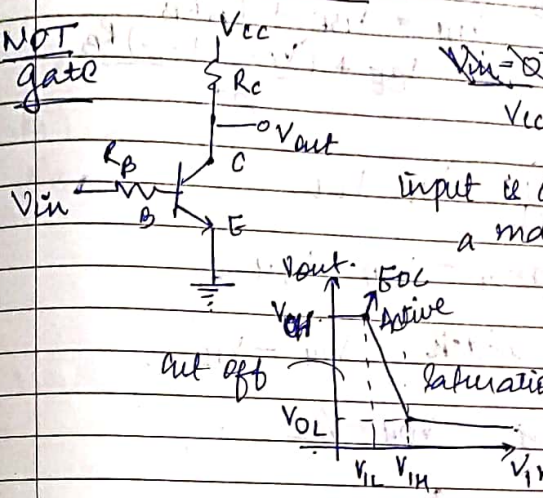
Propagation delay -
avg transition delay for signal to propagate from input to output when signal changes its value
↳ due to finite switching speed of trans. & capacitance



$t_{PD} = \frac{t_{PHL} + t_{PLH}}{2}$

Transistor as switch

NOT gate



$V_{in} = 0$:
$V_{CC} - I_C R_C = V_{out} = V_{CC}$
input is considered low to a max. point V_{IL}

$V_{in} = 1 \Rightarrow V_{IH} \Leftarrow$ min. voltage treated as logic high
$V_{out} = V_{OL}$

Cut off Base current $I_B = 0$ till $V_B - V_{in} < V_{IL}$
$V_{out} = V_{OH}$ over entire range.

Break point / edge of cutoff (EOC), point where $V_{in} = V_{IL}$, $V_{out} = V_{OH}$

Active $I_B = \frac{V_B - V_{out}}{R_B}$ $I_B = \frac{V_{in} - V_{BE}}{R_B}$

$I_C = \beta I_B$

$V_{out} = V_{CC} - \frac{\beta R_C (V_{in} - V_{BE})}{R_B}$

Saturation region -
Edge of saturation - $V_{in} = V_{IH}$, $V_{out} = V_{OL}$

$I_C = \frac{V_{CC} - V_{CE}}{R_C}$

$V_{IH} = V_{BE} + I_B R_B$

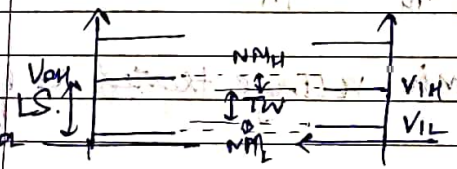
$= V_{BE} + \frac{(V_{CC} - V_{CE}) R_B}{\beta R_C}$

Noise margin)$_L$ $= V_{IL} - V_{OL}$

Noise margin)$_H$ $= V_{OH} - V_{IH}$

Transition width $= V_{IH} - V_{IL}$

Logic swing $= V_{OH} - V_{OL}$



Fan-out $= I_{C(drives)} / I_{B(load)}$

Static Power dissipation
- when transistor is either on/off
- depends on current drawn

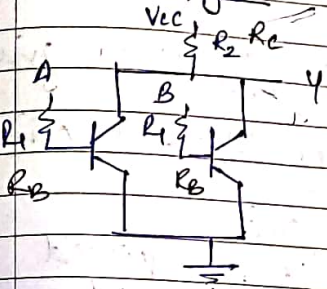
$E = P_0 \times t_{PD}$

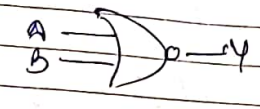
figure of merit — the lower, the better

- significant in switching of BJT

Dynamic Power dissipation
- depends on switching speed
- when transistor switches
- significant in switching of CMOS trans.

RTL NOR gate





For 3 input, another input will come in parallel between A & B.

more no. of inputs - more delay.

Fan-in: max. no. of inputs a gate can handle.

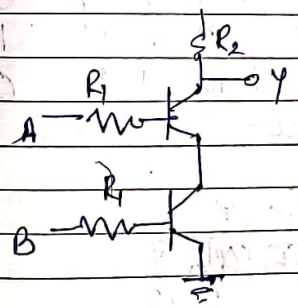
A	B	Y
0	0	1
0	1	0
1	0	0
1	1	0

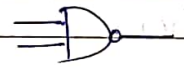
A=0=B ⇒ transistor is off

in all other cases, at least 1 trans. works ⇒ earthed.

= 0

RTL NAND gate





A	B	Y
0	0	1
0	1	1
1	0	1
1	1	0

If any one is off, ckt off ⇒ conduction doesn't occur

If both are on ⇒ earthed

Clocked Sequential Circuits

Steps – (1) State/timing diagram is given
(2) obtain state table
(3) reduce states by state reduction method.
(4) do state assignment
(5) determine no. of flipflops required
(6) decide type of flipflop required
(7) derive circuit excitation eqn.
(8) obtain expression for output & input
(9) implement circuit
